CASE

Re-ment is decarbonising cement without a green premium

Cemvision converts low-grade steel slag that would otherwise be waste into high-performance cement feedstock, while recovering valuable critical metals from steelmaking.

THE OPPORTUNITY

Laser focus for a massive climate challenge

Cement accounts for approximately 7 - 8% of global CO_2 emissions. Cemvision is targeting this specific problem with Re-ment. Its opportunity is to replace conventional cement in established construction applications without requiring customers to redesign their production processes or pay a green premium.

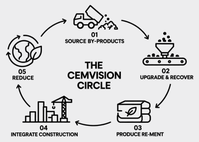

THE CIRCULAR MODEL

Turning steel slag into cement feedstock and valuable metals

Cemvision creates value across two industrial value chains: steelmaking and construction. Its technology upgrades low-grade slag into cement feedstock while recovering valuable metals, such as vanadium, that can be returned to industrial use.

By replacing virgin raw materials with industrial by-products, the process aims to reduce emissions, material waste and dependence on newly extracted resources.

BANKABILITY INDICATORS

Connecting technology, customers and capital

Cemvision shows how a focused industrial innovation can progress towards bankability when technical development is combined with customer validation, strategic partners and a financing path.
